# How to reduce load in microgrid

## Overview

---

This review examines critical areas such as reinforcement learning, multi-agent systems, predictive modeling, energy storage, and optimization algorithms—essential for improving microgrid efficiency.

This review examines critical areas such as reinforcement learning, multi-agent systems, predictive modeling, energy storage, and optimization algorithms—essential for improving microgrid efficiency.

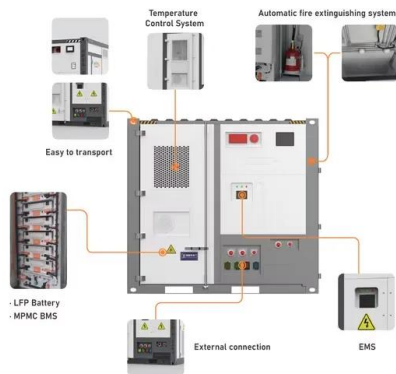

Strategies are presented for the classification of loads by criticality, identifying active vs. inactive loads and for maintaining near real time quantitative data for matching loads to generation. We discuss the need for active load control when in the microgrid is in grid paralleled operation, as well as when islanded.

To describe and reduce the risk of underfrequency load shedding more accurately in microgrids, more accurate assessment methods and models need to be developed, including further analysis and quantitative treatment of risk factors.

$m$  = number of generators in system.  $g$  = generator number, 1 through  $m$ .  $L$  = amount of load selected for.  $n$  = number of events (kW)  $P_n$  = power disparity caused by  $n$  event (kW)  $IRM_n$  = incremental reserve margin of all remaining generators after  $n$  events (kW) Inertial Based Load-Shedding Systems Operate when a Contingency Load Shedding System is out of .

The system uses the Al-Biruni earth radius (BER) optimization algorithm to make smart choices about how to distribute the load, intending to reduce energy consumption and costs without.
