Overview

One of the key technologies to maintain the performance, longevity, and safety of lithium-ion batteries (LIBs) is the battery thermal management system (BTMS). Owing to its excellent conduction and high temperature stability, liquid cold plate (LCP) cooling technology is an effective BTMS solution.

One of the key technologies to maintain the performance, longevity, and safety of lithium-ion batteries (LIBs) is the battery thermal management system (BTMS). Owing to its excellent conduction and high temperature stability, liquid cold plate (LCP) cooling technology is an effective BTMS solution.

Thermal management is indispensable to lithium-ion battery pack esp. within high power energy storage device and system. To investigate the thermal performance of lithium-ion battery pack, a type of liq. cooling method based on mini-channel cold-plate is used and the three-dimensional numerical model was established in this paper.

The liquid immersion cooling method, which relies on a two-phase heat transfer, has a much higher heat-transfer efficiency than FAC. SF33 immersion cooling is effective in absorbing the substantial thermal energy produced by a cell battery during high C-rate discharge, while preserving the optimal temperature range of 33–34 °C.

Today, indirect liquid cooling is a common method of dissipating heat in the BTMS of new energy vehicles. There are two main implementation methods, shown in Figure 18: (1) dissipating heat through the tubes or tube sheets in the battery pack [81,82,83] and (2) installing the batteries on the liquid cooling plate [84,85,86]. These two methods .

This study proposes a stepped-channel liquid-cooled battery thermal management system based on lightweight. The impact of channel width, cell-to-cell lateral spacing, contact height, and contact angle on the effectiveness of the thermal control system (TCS) is investigated using numerical simulation. The weight sensitivity factor is adopted to .
