Microgrid random power flow calculation

Overview

What is the penetration coefficient of microgrids in power systems?

The penetration coefficient of microgrids in power systems, as well as the high uncertainty of these sources, requires an analysis of probabilistic methods. These types of energy sources are inherently uncertain and bring many unknowns to the power system.

What is probabilistic power flow?

Probabilistic power flow (PPF) is an effective method to evaluate the steady state of power systems with uncertainties [10]. The Monte Carlo simulation (MCS) [11], [12], [13], point estimate method (PEM) [14], [15], [16] and cumulant method (CM) [17], [18] are widely used in PPF calculation.

What is data clustering based probabilistic assessment method of power system?

In , the authors propose a data clustering based probabilistic assessment method of power system in probabilistic optimal power flow problem and evolutionary based optimization method is used to reduce the complexity and improve the convergence process of the optimal power flow calculation.

How do you calculate power flow in a power system?

There are many methods for calculating the power flow in power systems that differ in speed, accuracy, and computer storage requirements. Optimization is the process of finding the best solution to a problem. Various methods have been used to this effect, as is the case of the MCM, 2PEM and 3PEM.

How is the distribution of power load profile calculated?

In , the distribution of power load profile is calculated through a Gaussian mixed model and the parameters of the model are set with a modified variational Bayesian inference (VBI) method.

Which methods are used to distribute possible loads in power systems?

This research examines some methods for the distribution of possible loads in power systems, namely the Monte Carlo method (MCM), the two-point estimation method (2PEM), and the three-point estimation method (3PEM). Then, these methods are used to distribute the possible POPF.
