# Photovoltaic panel spots

## Overview

---

In a photovoltaic (PV) module, a hot spot describes an over proportional heating of a single solar cell or a cell part compared to the surrounding cells. It is a typical degradation mode in PV modules. .

Hot spots can origin, if one , or just a part of it, produces less compared to the other cells connected in . This may occur due to partially shading, dirt on the module (leaf, bird drop) or cell.

Quick detection is possible with infrared camera, performing . A hot spot can also lead to browning in the glass plane of the PV module, if it is present for long time. Thus, the hot spot can become visible for the human eye. To prevent emergence.

Hotspots are localized temperature increases in solar panels that can seriously impact their performance.

Hotspots are localized temperature increases in solar panels that can seriously impact their performance.

Hot spots in solar panels can arise from shading, manufacturing defects, cell degradation, and electrical mismatches, leading to localized heating and potential performance issues.

Hot spots happen when certain areas of a solar panel get much hotter than others. This can be caused by uneven sun exposure, electrical issues, or debris buildup.
