## Overview

---

Curtailment occurs when a solar photovoltaic (PV) system generates more electricity than the local grid or infrastructure can effectively handle. This excess energy is essentially wasted or deliberately curtailed to prevent overloading the grid, and it can happen for a variety of reasons:

Curtailment occurs when a solar photovoltaic (PV) system generates more electricity than the local grid or infrastructure can effectively handle. This excess energy is essentially wasted or deliberately curtailed to prevent overloading the grid, and it can happen for a variety of reasons:

PV curtailment is often framed as a loss given that effectively free and clean electricity goes unused (Bird et al., 2016, Henriot, 2015). Curtailment may also undermine PV project economics and could hinder future PV deployment (Golden and Paulos, 2015). As a result, various grid and market practices discourage curtailment.

At increasing levels of PV penetration situations arise where PV is curtailed, either because of local supply/demand imbalances or to maintain system flexibility. In this paper, we present a novel synthesis of recent curtailment in four key countries: Chile, China, Germany, and the United States.

Most PV curtailment stems from some system constraint that impedes the grid from absorbing more PV output. 1 To build some intuition around how system constraints can drive curtailment, Fig. 1 depicts an actual PV curtailment event in California in May 2018. As PV came online at 6 am, some flexible generators—mostly imports and natural gas .

Here, we focus on PV for two reasons: (1) it is poised to provide the largest share of new VRE deployed in the United States 28, 29 and many other countries, 30 and (2) it shows a more rapid increase of curtailment with penetration because of itsWhat is solar photovoltaic (PV) & how does it work?

Solar photovoltaic (PV) systems generate electricity with no marginal costs or emissions. As a result, PV output is almost always prioritized over other fuel sources and delivered to the electric grid. However, PV curtailment is

increasing as PV composes greater shares of grid capacity.

How do policy and grid planning practices influence PV curtailment?

We find that: Policy and grid planning practices influence where, when, and how much PV is curtailed; Some PV curtailment is attributable to limited transmission capacity connecting remote solar resources to load centers; PV curtailment peaks in the spring and fall, when PV output is relatively high but electricity demand is relatively low.

Can a more flexible grid reduce PV curtailment?

Larger coordinated systems can manage PV output to reduce curtailment. Flexibility refers to the ability of a grid to respond to changes in the supply and demand of electricity ( Cochran et al., 2014 ). All else equal, a more flexible grid is able to accommodate more PV without resorting to curtailment than a less flexible grid.

How does PV curtailment affect grid capacity?

Each marginal unit of PV output pushes down the midday net load, making it more likely that PV output will exceed the grid's ability to absorb that output during the solar peak. As a result, PV curtailment is projected to increase as PV composes greater shares of grid capacity ( Denholm et al., 2015 ).

How does PV oversupply affect the grid?

Oversupply risk generally increases as more PV is integrated onto the grid ( Denholm et al., 2016, Nelson et al., 2018 ). Each marginal unit of PV output pushes down the midday net load, making it more likely that PV output will exceed the grid's ability to absorb that output during the solar peak.

Why do we need advanced inverter functions for PV curtailment?

However, these phenomena also provide conditions for PV curtailment, where high penetrations of distributed PV often necessitate the use of advanced inverter functions with VAR priority to address abnormal grid conditions like over-and under-voltages.
